

# VirtualBox 6.0

Turns out, VirtualBox 6.0 was released on December 18th, 2018.

Looking at the release notes I have found the following interesting features that I've yet to try:

## VirtualBox 6.0

- **Nested virtualization** – available only on AMD CPUs for now – this allows you to install a hypervisor like KVM or VirtualBox inside a VirtualBox guest VM – this still needs [hw virtualization](#).
- **Hyper-V support** – apparently, VirtualBox will detect if it's running on a Windows server with Hyper-V activated, and will use Hyper-V as virtualization engine – albeit, it might run slower than native VirtualBox or Hyper-V guest VMs
- **Moving stuff** – both disk images and VM metadata can now

be moved very easily to a new location

- **Closing VMs improved** – there's now an option to keep the same hardware UUID when closing a guest VM
- **FUSE mount for vdisk images** – on Mac OS hosts it's possible to use a `vboximg-mount` command for raw access to the virtual disks

I've updated my [VirtualBox software](#) page with the above notes and will be testing features and sharing.
